## ABSTRACT

The National Health Interview Survey (NHIS) is a multipurpose household survey of the US civilian non-institutionalized population conducted annually since 1957. From 1997-2004, 153,393 US workers age 18 years and older (representing an estimated 126,637,406 US workers annually) participated in a probability sampling of the entire non-institutionalized US population; variables collected included a range of measures of health disparities.

The objective of this Monograph was to review the health disparities experience for US workers by occupation using the 1997-2004 NHIS. After adjustment for sample weights and design effects using SUDAAN, the prevalence rates (with their standard errors) of a variety of measures of health disparities were examined. For the purposes of this Monograph, health disparities endpoints included: a mixture of disability (i.e. missed work days, bed days and self-reported health) and health measures (i.e. the reported prevalence of hypertension, heart disease, stroke, emphysema, asthma, cancer, and diabetes). These health disparity measure prevalence rates have been presented by occupational subgroups, as well as by age, gender, race, ethnicity, and availability of medical insurance subgroups within each occupation. Furthermore, the occupational data are presented by 3 different levels of occupation/industry groupings: 13 and 41 occupations, and the new NIOSH National Occupational Research Agenda (NORA) 8 industry groups. Extrapolation to the entire US worker population for these data during the 1997-2004 time period is also made available. The Study Website (**http://www.UMiamiOrg.com)** contains a repository of interactive tables which are available in both Excel and PDF formats; additional study and NHIS documentation are also available at this Website.

Understanding the occupational risk factors and improving the health of US workforce remains a public health priority. Occupational surveillance using the NHIS dataset allows for the careful monitoring of these occupational risk factors in order to identify prevention strategies and to minimize health disparities among US workers and their families.

## KEY WORDS

Health Disparities, Disability, Race, Ethnicity, Socio-Economic Class, Education, Health Insurance, Morbidity, Occupation, Industry, National Health Interview Survey (NHIS), Surveillance, NORA

## ACKNOWLEDGMENTS

The data for the National Health Interview Survey (NHIS) were originally collected and prepared by the US Dept of Health and Human Services and the National Center for Health Statistics which does not bear any responsibility for the analyses or interpretations presented in this publication This study was funded in part through the National Institute of Occupational Safety and Health (NIOSH) Grant number 1 R01 0H03915-01. Additional information on this study can be found at the Study Website located at: **http://www.UMiamiORG.com**.

## INTRODUCTION

It is recognized that a variety of occupational and environmental risk factors interact to determine the overall health and well being of the US workforce. Occupational health surveillance is poised to document these interactions by systematically collecting, analyzing, and interpreting health data essential to the planning, implementation and evaluation of public health strategies to maximize workforce health. These robust surveillance systems collect and maintain health outcome information for all members of a temporally and geographically defined population at risk. The Research Group at the University of Miami is funded by the National Institute for Occupational Safety and Health (NIOSH) to utilize the National Health Interview Survey (NHIS) dataset collected and conducted by the National Center for Health Statistics (NCHS) at the Centers for Disease Control (CDC) to study the health of all US workers.

The National Health Interview Survey (NHIS) is a continuous multipurpose and multistage probability area survey of the US civilian non-institutionalized population living at addressed dwellings (NCHS; Kaminski and Spirtas 1980; Botman and Jack 1995; Botman, Moore et al. 2000). Each week a probability sample of households is interviewed by trained personnel to obtain information about the characteristics of each member of the household.(Liao, Cooper et al. 1998) Data from the 1997-2004 NHIS Surveys included a range of measures of acute and chronic disability collected in depth for one member of the household. Recently, the NHIS conducted a data linkage with the National Death Index resulting in mortality follow up information including cause of death through 2002 for approximately 97% of the NHIS survey population from 1986-2000. The NHIS database allows for longitudinal analysis of mortality data as a retrospective cohort study, as well as for cross-sectional and secular trend analyses of the aggregate morbidity data. Thus, the NHIS database represents a unique opportunity to explore new research hypotheses, and to use the data as a surveillance tool to evaluate time trends and occupational disease and mortality in the US for the past 2 decades in both genders and in a variety of race-ethnic and socio-economic subpopulations.

Race-ethnicity and socio-economic status health disparities in occupational health have not been fully investigated.(Murray 2003; Kilbourne, Switzer et al. 2006) Although significantly under-reported, occupational disease, injury, and mortality represent important health factors for US workers and their families. The Bureau of Labor Statistics estimated at least 5,524 traumatic occupational deaths and over 6 million work related injuries and diseases in the public and private sector of the US work force in 2002.(BLS 2006) However, the risks for occupational mortality and morbidity are not evenly distributed.(Murray 2003) It appears that these risks disproportionately affect US workers from specific race-ethnicity subpopulations and from lower socio-economic classes.

This Health Disparities Monograph establishes and applies a methodology to assess prevalence rates of a number of disability and health conditions associated with health disparities during the 1997-2004 time period for US workers by occupation. After adjustment for sample weights and design effects, the prevalence rates were created in tabular format. These prevalence rates have been presented by different occupational groups (including the new NIOSH NORA industry classifications), as well as by age, gender, race, ethnicity, and insurance availability. These data have also been extrapolated to the entire US worker population during the 1997-2004 time period.

## BACKGROUND

The European countries, particularly England since 1837 in their Registrar General's Decennial Supplements for England and Wales, have had a long history of performing nationwide occupational studies.(Drever 1995) As noted in the 1995 Registrar General's Report (Drever 1995), these data have provided a valuable means of generating hypotheses about work-related risks to health as well as insight in the effectiveness of preventive measures. These studies have provided important documentation of a socioeconomic gradient of mortality, where those who are of lower social class have higher rates of death. The United States has had relatively few studies of equal scope and caliber to evaluate the causes of morbidity and mortality, and their trends, in US workers. (Guralnick 1962; Guralnick 1963; Milham 1976; Kaminski and Spirtas 1980; Milham 1983; NIOSH 1983; Gallagher 1989; NIOSH 2004)

In the US, as in other industrialized countries, there has been a large number of studies of the mortality and morbidity rates of particular industries or groups of workers. Traditionally, occupational epidemiologic studies of mortality and morbidity have focused on cohorts of workers at particular industrial worksites, due to the relative ease of access to data.(Dell and Teta 1995; Honda, Delzell et al. 1995; Tsai, Gilstrap et al. 1996; Chiazze, Watkins et al. 1997; Gold and Kathren 1998) Research has also been performed on the causes of mortality and morbidity for white male workers in large occupational groups, such as chemical workers and construction workers. (Blair, Dosemeci et al. 1993; Robinson, Stern et al. 1995; Steenland and Brown 1995; Kross, Burmeister et al. 1996; Suruda and Wallace 1996; Matanoski, Kanchanaraksa et al. 1998; Savitz, Checkoway et al. 1998) In addition, studies have demonstrated morbidity and mortality trends for US workers in specific geographic areas.(Milham 1976; Hwang, Fitzgerald et al. 1995; Fleming 1999) Although a number of international studies on worker morbidity/mortality have been completed (Engholm and Englund 1995; Schouten and Borgdorff 1995; Kagamimori, Matsubara et al. 1998), very little research has been performed on the entire US workforce, mainly due to the lack of large and appropriately selected samples. Therefore, studies of the health status of the US worker have been confined to certain industry/worker groups, and/or geographic areas.

A modest collection of recent studies have considered the impact of workforce characteristics such as age, race-ethnicity, gender, and socio-economic class on the US workforce as a whole. Recent health disparity studies have shown that older age, certain race-ethnic groups, lower socio-economic class, and even some female subpopulations are at increased risk for disability and mortality compared to their counterparts.(Wagener and Winn 1991; Bollini and Siem 1995; Zwerling, Sprince et al. 1995; Zwerling, Sprince et al. 1996; Zwerling, Sprince et al. 1996; King, Borrelli et al. 1997; Wagener, Walstedt et al. 1997; Zwerling, Whitten et al. 1997; Zwerling, Sprince et al. 1998; Zwerling, Whitten et al. 1998; Frumkin and Pransky 1999; Pollan and Gustavsson 1999; Khlat, Sermet et al. 2000; Keppel, Pearcy et al. 2002; Janzen and Muhajarine 2003; Murray 2003; Steenland, Burnett et al. 2003; Steenland, Halperin et al. 2003; Zwerling, Whitten et al. 2003; Barbeau, Krieger et al. 2004; O'Campo, Eaton et al. 2004)

### Health Disparities and Worker Subpopulations

Health disparities represent a burgeoning area of research which recognizes and seeks to eliminate differences in the morbidity and mortality risks and experiences of women, the elderly, and different race-ethnic and socio-economic subpopulations in the US.(House 2002; Keppel, Pearcy et al. 2002) Health disparities appear to be associated with a wide range of factors including: the individual's demographic factors (such as age and gender), socio-economic class and race-ethnicity, and access to high quality prevention and healthcare. A key objective of the Healthy People 2010 is, **"to eliminate health disparities among segments of the population including differences that occur by gender, race or ethnicity, geographic location, or sexual orientation"**.(2000) As noted

by Barbeau et al. (Barbeau, Krieger et al. 2004), this key objective does not identify **occupation as a significant factor in health disparities** in the US.

Occupation is often linked with socio-economic class (including education and income). However, occupation can be an important independent health determinant directly in terms of hazardous exposures, and indirectly in terms of influencing health behavior. For example, Barbeau et al. (Barbeau, Krieger et al. 2004; Barbeau, McLellan et al. 2004) noted that the prevalence of cigarette smoking was independently associated with occupation, educational level and income level. There can be varying occupational morbidity and mortality risks by different gender and race-ethnic subpopulations. Loomis and Richardson (Loomis and Richardson 1998) found that African American men had an increased risk of occupational injury mortality, even taking into account differing employment patterns by occupation. Unequal distribution of risk and explicit discrimination within occupations, as well as inequalities in access to the labor market, are potential explanations for these differences in occupational risk among occupational race-ethnic subpopulations. Nevertheless, as noted by Murray (Murray 2003) and others (Ward, Jemal et al. 2004), there has been relatively little research into this area particularly at the national level. Therefore, the NHIS database with the extended mortality follow up provides a unique opportunity to explore morbidity and mortality risks by different genders and race-ethnic subpopulations among different occupations.

Although women have been the majority of the civilian non-institutionalized US adult population since 1950 and approximately half the labor force since 1990, as discussed above, relatively few studies have considered morbidity/mortality issues specific to women workers.(Wagener, Walstedt et al. 1997; O'Campo, Eaton et al. 2004) In general, women have been assumed to be healthier than men, but this may not hold true for working women of particular race-ethnic subpopulations and among women working in traditional male occupations.(Murray 2003) It has been shown that women are paid less than men for the same jobs, even accounting for education, training, and job experience.(Valian 1998) In addition to income inequality, a few studies examining female US workers and their health and disability status found potential gender health inequalities.(Peterson and Zwerling 1998; Valian 1998; Khlat, Sermet et al. 2000; Janzen and Muhajarine 2003; O'Campo, Eaton et al. 2004)

In the US, race-ethnic health disparities reflect, to a large degree, socio-economic differences that have a substantial impact on many aspects of health status, especially in terms of prevention and intervention.(Berkman and Macintyre 1997; Barbeau, Krieger et al. 2004) For example, workers of race-ethnic subpopulations are more likely to work in lower paying and potentially more dangerous jobs: in 1996, 50% of sanitation workers and 33% of nurses' aides were black, while 37% of all farm workers were Hispanic.(Murray 2003) Furthermore, although relatively little occupational research exists, even within particular occupations or industries, race-ethnic, socio-economic and female subpopulations appear to experience varying health status and mortality rates compared to the white male US worker.(Frumkin and Pransky 1999) For example, recent studies have found increased risk among certain race-ethnic US worker subpopulations for occupational cancer, fatal injury, lower back pain, occupational asthma and asthma mortality, and lead poisoning, among other diseases.(Loomis and Richardson 1998; Prout, Wesley et al. 2000; Schulz and Loomis 2000; Elmarsafawy, Tsaih et al. 2002; Keppel, Pearcy et al. 2002; Briggs, Levine et al. 2003; Steenland, Burnett et al. 2003; Steenland, Halperin et al. 2003; Stellman, Chen et al. 2003)

Although laudable, this research is subject to certain key limitations including selective reporting, the use of occupation at time of death as the definition of occupational exposure, focusing purely on traumatic injury, and/or lack of generalizability to the entire US workforce due to sampling issues. As noted by Kaminski and Spirtas (Kaminski and Spirtas 1980), the National Health Interview Survey (NHIS) is a nationally representative dataset, that can be used as a surveillance system for occupational disease morbidity and mortality for all US workers, and they recommended that its use

for this purpose be explored further.

## METHODS

### The National Health Interview Survey (NHIS)

Since 1957, the National Center for Health Statistics (NCHS) has annually administered the National Health Interview Survey (NHIS), a continuous multipurpose and multistage area probability survey of the US civilian non-institutionalized population living at addressed dwellings.(Botman and Jack 1995; Botman, Moore et al. 2000) The survey was authorized by Congress in order to obtain national estimates on disease, injury, impairment, morbidity, mortality, health behaviors, and related issues on a uniform basis for the entire US population.(Fowler 1996) The NHIS Survey has evolved over the years (as described below), with a significant redesign in 1997.

#### *NHIS Annual Survey 1986-1994*

During the 1986-1994 period, each week a probability sample of households was interviewed by trained personnel to obtain information about the characteristics of each member of the household. The NHIS collected basic health data in four main areas including: hospitalizations, use of medical services, effects of health on functioning, and the presence of acute and chronic health conditions. (Botman and Jack 1995; Fowler 1996; Botman, Moore et al. 2000) These questions were relatively unchanged over the 1986-94 survey period. The NHIS also included periodic supplements on special health topics; for example, in 1988, NIOSH and the NCHS collaborated on an Occupational Health Supplement.(Massey, Moore et al. 1989; Landen and Hendricks 1992)

Households were selected by a multi-stage probability sampling strategy involving both clustering and stratification and designed to provide a representative sample of US adults.(Massey 1989; Massey, Moore et al. 1989) Approximately 50,000 households and 120,000 persons were interviewed annually using a primary household respondent, with all adults in the home participating in the interview. For the 1986-1994 surveys, some data for individuals were obtained by proxy (i.e., from the primary household respondent) if not all adults were present in the household at the time of the interview. For the 1986-1994 surveys, household response rates exceeded 90%, and the data can be analyzed at the individual or family level.(Atrostic, Bates et al. 1999)

In addition to a wide range of self-reported demographic and health data, the NHIS annual surveys contained substantial information concerning employment. There was considerable exploration as to the current employment status, as well as assignment of the appropriate industry and occupation codes for each participant. During this period of time, the NHIS used current employment status during the 2 weeks prior to interview for all persons 18 years or older to categorize into occupational groups.(Brackbill, Frazier et al. 1988)

The Research Group has published extensively using the 1986-1994 NHIS data (including the mortality follow up through 2002); links to these publications can be found at the Study Website located at: **http://www.UMiamiORG.com**.

Due to major design issues (including occupational coding), the data from the 1995 and 1996 NHIS are not used by the Research Group.

#### *NHIS Annual Survey 1997-2004*

Following incremental modifications in the 1995 and 1996 surveys (rendering these 2 years difficult to analyze), the NHIS was completely redesigned in 1997. The redesigned NHIS collects key health information from a single randomly selected adult household member (using the “Adult Questionnaire”). This strategy greatly enhances the reliability of acute and chronic condition assessment; it includes individual level information for all participants on functional status, health conditions, physical and social activity limitations, psychological distress, chronic conditions and

recent injuries, important risk factors (such as tobacco and alcohol use), and access to care. In addition to better information on health conditions, this new NHIS information will allow for greater exploration of morbidity and health behaviors of all US workers. The annual response rates to the 1997-2004 adult core have ranged from 70% in survey year 1999 to 80% in survey year 1997.(Blackwell, Collins et al. 2002; Pleis and Coles 2002; Pleis, Benson et al. 2003; Pleis and Coles 2003; Lethbridge-Cejku, Schiller et al. 2004; Lucas, Schiller et al. 2004)

In the NHIS, "disability days" were defined as missing work because of illness or injury (not including maternity leave) over the last 12 months; "bed days" were defined as the number of days in which an illness or injury kept the participant in bed for more than half of the day (including days spent overnight as a patient in a hospital). For the present analyses, the overall prevalence (with standard error) as well as the prevalence for 0, 1-2, and 3+ disability and bed days were presented (see Tables 2-5; 7-8).

In addition, a general question was asked about current self-rated health status (i.e. excellent, very good, good, fair, and poor), as well as the reported lifetime prevalence of ever having been told by a doctor that the participant suffered from hypertension (or high blood pressure), heart disease, stroke, emphysema, asthma, cancer, and diabetes. Of note, for the purposes of this study, "self rated health" was defined as either good (ie. excellent, very good or good) or poor (i.e. fair or poor), and "heart disease" was defined as the combination of any affirmative answer to ever having been told by a doctor that the participant suffered from: coronary heart disease, angina pectoris, heart attack (also called myocardial infarction), or any kind of heart condition or heart disease. For each of the disability and health variables, analyses were performed for specific occupations (13 and 41), for the 8 NORA industry categories, and by age, gender, race, ethnicity, and availability of insurance.

During the 1997-2004 interview period, the NHIS used current employment status (paid and unpaid) during the 1 week prior to interview for all persons 18 years or older.(Kaminski and Spirtas 1980; Brackbill, Frazier et al. 1988; Zwerling, Whitten et al. 1997) Standardized Occupational Codes (really US Census codes) were provided in the NHIS database (NCHS 1992; NCHS 1998), as well as various NHIS recodes with less detailed occupational codes. For the purpose of this study, the 13 and 41 NHIS occupational categories were used. In addition, the new National Occupational Research Agenda (NORA) industry categories, which will guide occupational research priorities at NIOSH for the next decade and beyond, have been used. The NORA categories are focused on the health and safety issues of 8 Sectors of industry (Agriculture, Mining, Construction, Manufacturing, Wholesale and Retail Trade, Transportation/Warehousing/Utilities, Services, and Healthcare and Social Assistance). (Sorerholm 2006) Each Sector Research Council has been mandated to identify its own issues and goals (as well as common research issues which cut across sectors, including worker health surveillance and worker health disparities).

Table 1 (See Appendix) presents the number of workers who participated in the NHIS survey pooled over the 1997-2004 period ("sample size") and the estimated/extrapolated number of workers these participants represented in the US worker population during this time period ("estimated US worker population") by age, gender, race, ethnicity, and insurance availability subpopulations. Of note, tables for the 13 and 41 occupational and NORA groups are available at the Study Website (**www.UMiamiORG.com**).

**Statistical Methods**

Because of the multi-stage sampling design, all analyses were performed with adjustment for sample weights and design effects using the SUDAAN statistical package.(RTI 2004) The sample weights used were those required for the analysis of data from combined survey years and were calculated as specified by Botman and Jack (Botman and Jack 1995; Botman, Moore et al. 2000).

***Data Tables and Use***

The Health Disparity data are presented in Tables 2-8 for each of the 2 levels of major US occupational groupings (i.e. 13 and 41) and by the 8 NORA Industry groups.

For pooled prevalence estimates, sample weights were adjusted to account for the aggregation of data over multiple survey years by dividing the original weight by 7 (the number of years combined in survey years 1997 through 2004).(Fowler 1996) It should be noted that prevalence rates with less than 25-45 individuals/occupational subpopulation can result in very unstable point estimates and corresponding standard errors. Furthermore, because of the sample weighting of the NHIS, in some instances a very small standard error, including a value of "0.0" might result. Therefore, analyses based on small numbers of workers should be interpreted with caution.

These unique data tables have been made available in two file formats: Portable Document Format (PDF) and Excel Spread Sheets (Excel) at the Study Website (URL: **http://www.UMiamiORG.com**). The PDF format allows researchers to quickly view and print the current table layouts, while the Excel format can be utilized to download the files to a remote computer and manipulate the data table locally.

To save an Excel file to a local computer system, the Study Website user can right click with their mouse over a link, at which time a dialog box will appear. Select the “Save target as” option to save the file from the Study website to the local system. A file viewer for PDF files is readily and freely available at the following website **http://www.adobe.com/products/acrobat/readstep2.html**. Researchers can utilize these additional data tables to further explore the health disparities experienced among this population-based sample and extrapolate to the general US workforce. As discussed above, the Standard Errors (SEs) presented in the Tables for the prevalence rates are presented. These SEs can be used to generate 95% confidence intervals (CI) of the prevalence estimates (i.e., 1.96 x ± SE). Multiplying the population estimates for a given worker population by the 95% CI will provide the lower and upper estimate of the number of workers for a given condition.

## RESULTS

From 1997-2004, 153,393 US workers age 18 years and older (representing an estimated 126,637,406 US workers annually) participated in a probability sampling of the entire non-institutionalized US population (Table 1). The results presented below summarize the prevalence for the health disparities measures (± their corresponding standard errors [SE]) during the study period 1997-2004 for each of the occupational groupings (i.e. 13 and 41) and the 8 NORA industry groups. For each occupation and NORA industry group, all tables report the data by age, gender, race, ethnicity, and availability of insurance as well as for total populations (See Appendix for Tables 1-8).

### Disability

#### *Lost Work Days*

13 Occupations: In Table 2, the prevalence for at least one lost work day by the different occupations is presented by age, gender, race, ethnicity, and insurance availability as well as by the US population overall. Among the 13 occupations, Administrative support occupations, including clerical workers, experienced the highest overall prevalence of lost work days (54.98±0.39), while Farming, forestry, fishing workers experienced the lowest (30.01±0.94). Among the age-gender-race-ethnicity-insurance availability subgroups, Female Technicians/related support workers experienced the highest overall prevalence (57.59±1.11), while Male Private household workers experienced the lowest (16.98±7.59).

41 Occupations**:** In Table 2, the prevalence for at least one lost work day by the 41 different occupational categories is presented by age, gender, race, ethnicity, and insurance availability as well as by the US population overall. Among the 41 occupations, Officials and public administration workers experienced the highest overall prevalence of lost work days (58.60±1.77), while Farm operators and managers workers experienced the lowest (24.15±1.35). Among the age-gender-race-ethnicity-insurance availability subgroups, other race Other transportation except motor vehicles workers, experienced the highest overall prevalence (78.20±22.71), while 65 years and older Computer equipment operators, and 65 years and older Other transportation except motor vehicles workers experienced the lowest (0.00±0.00 based on an n of 1 and 2, respectively).

8 NORA Industry Groups: In Table 2, the prevalence for at least one lost work day by the different occupations is presented by age, gender, race, ethnicity, and insurance availability as well as the estimated US population numbers. Among the NORA Sectors, Healthcare and social assistance workers experienced the highest overall prevalence of at least one lost work day (51.84±0.44), while Agriculture, forestry, fishing workers experienced the lowest (30.53±0.95). Among the age-gender-race-ethnicity-insurance availability subgroups, female Mining workers experienced the highest overall prevalence (57.68±6.94), while other race Agriculture, forestry, fishing workers experienced the lowest (20.01±3.79).

In addition, in Tables 4 and 7, the prevalences for lost work days divided by different categories (ie. 0, 1-2, 3+ days) are presented for each occupation and NORA industry group, all tables report the data by age, gender, race, ethnicity, and availability of insurance as well as for the total populations.

#### *Bed Days*

13 Occupations: In Table 2, the prevalence for at least one bed day by the different occupations is presented by age, gender, race, ethnicity, and insurance availability as well as the estimated US population numbers. Among the 13 occupations, Administrative support occupations including clerical workers experienced the highest overall prevalence of at least one bed day (43.29±0.42), while Farming, forestry, fishing workers experienced the lowest (24.52±0.91). Among the age-gender-

race-ethnicity-insurance availability subgroups, female Professional specialty workers experienced the highest overall prevalence (47.03±0.49), while Hispanic Farming, forestry, fishing workers experienced the lowest (14.58±1.12).

41 Occupations**:** In Table 2, the prevalence for at least one bed day by the different occupations is presented by age, gender, race, ethnicity, and insurance availability as well as the estimated US population numbers. Among the 41 occupations, Other professional specialty Occupations workers experienced the highest overall prevalence of at least one bed day (45.55±1.01), while Farm operators and managers experienced the lowest (21.22±1.39). Among the age-gender-race-ethnicity-insurance availability subgroups, other race Architects and surveyors workers experienced the highest overall prevalence (64.00±13.89), while 65 year and older Computer equipment operators and other race Other transportation except motor vehicles workers experienced the lowest (0.00±0.00 based on an n of 1 and 2, respectively).

8 NORA Industry Groups: In Table 2, the prevalence rate for at least one bed day by the different occupations is presented by age, gender, race, ethnicity, and insurance availability as well as for the US population overall. Among the NORA Sectors, Healthcare and social assistance workers experienced the highest overall prevalence (42.09 ±0.42), while Agriculture, forestry, fishing workers experienced the lowest (25.15 ±0.88). Among the age-gender-race-ethnicity-insurance availability subgroups, other race Mining workers experienced the highest overall prevalence (58.27± 13.61), while other race Agriculture, forestry, fishing workers experienced the lowest (14.26 ± 2.67).

In addition, in Table 5 and 8, the prevalences for bed days divided by different categories (ie. 0, 1-2, 3+ days) are presented for each occupation and NORA industry group, all tables report the data by age, gender, race, ethnicity, and availability of insurance as well as for the total populations.

**Health**

***Poor self rated health***

13 Occupations: In Table 2, the prevalence rate for poor self-rated health by the different occupations is presented by age, gender, race, ethnicity, and insurance availability as well as for US population overall. Among the 13 occupations, Private household workers experienced the highest overall prevalence of poor self-rated health (40.48 ±1.81), while Professional specialty workers experienced the lowest (18.68±0.29). Among the age-gender-race-ethnicity-insurance availability subgroups, 65 year and older Transportation/ material moving workers experienced the highest overall prevalence (54.54±3.25), while male Professional specialty workers experienced the lowest (17.19±0.40).

41 Occupations**:** In Table 2, the prevalence of poor self-rated health by the different occupations is presented by age, gender, race, ethnicity, and insurance availability as well as for the US population overall. Among the 41 occupations, Health service workers experienced the highest overall prevalence of poor self-rated health (41.86±0.99), while Health diagnosing occupation workers experienced the lowest (9.91±0.94). Among the age-gender-race-ethnicity-insurance availability subgroups, 65 year and older Forestry and fishing workers experienced the highest overall prevalence (64.77±16.96), while 65 year and older Computer equipment operators and 65 year and older Other transportation except motor vehicles workers experienced the lowest (0.00±0.00 based on an n of 1 and 2, respectively).

8 NORA Industry Groups: In Table 2, the prevalence of poor self-rated health by the different occupations is presented by age, gender, race, ethnicity, and insurance availability as well as the estimated US population numbers. Among the NORA Sectors, Agriculture, forestry, fishing workers experienced the highest overall prevalence of poor self-rated health (31.90±0.83), while Service workers experienced the lowest (24.82±0.24). Among the age-gender-race-ethnicity-insurance

availability subgroups, 65 year and older Mining workers experienced the highest overall prevalence (59.64±11.70), while other race Mining workers experienced the lowest (9.94±6.16).

In addition, in Table 6, the prevalences for each self-reported health category (i.e. poor, fair, good, very good, and excellent) are presented for each occupation and NORA industry group, all tables report the data by age, gender, race, ethnicity, and availability of insurance as well as for the total populations.

***Hypertension***

13 Occupations: In Table 3, the prevalence for hypertension by the different occupations is presented by age, gender, race, ethnicity, and insurance availability as well as the estimated US population numbers. Among the 13 occupations, Transportation/ material moving workers experienced the highest overall prevalence (21.71±0.62), while Handlers, equipment cleaners, helpers, laborers workers experienced the lowest (13.66 ± 0.52). Among the age-gender-race-ethnicity-insurance availability subgroups, 65 year and older Protective service workers experienced the highest overall prevalence (55.01±5.20), while Hispanic Handlers, equipment cleaners, helpers, laborers workers experienced the lowest (7.91±0.70).

41 Occupations**:** In Table 3, the prevalence of hypertension by the different occupations is presented by age, gender, race, ethnicity, and insurance availability as well as the estimated US population numbers. Among the 41 occupations, Other protective service occupations workers experienced the highest overall prevalence (24.18±1.40), while Architects and surveyors experienced the lowest (11.18±2.15). Among the age-gender-race-ethnicity-insurance availability subgroups, 65 year and older Computer equipment operators workers experienced the highest overall prevalence (100.00±0.00), while other race Forestry and fishing occupations, and other race, Hispanic, 65 and older, and Insured Other transportation except motor vehicles workers experienced the lowest (0.00±0.00 based on an n of 7, 4, 6, 2, and 8, respectively).

8 NORA Industry Groups: In Table 3, the prevalence of hypertension by the different occupations is presented by age, gender, race, ethnicity, and insurance availability as well as the estimated US population numbers. Among the NORA Sectors, Mining workers experienced the highest overall prevalence of hypertension (19.18±1.99), while Wholesale and retail trade workers experienced the lowest (14.42±0.28). Among the age-gender-race-ethnicity-insurance availability subgroups, 65 year and older Mining workers experienced the highest overall prevalence (51.74±11.68), while Hispanic Construction workers experienced the lowest (8.19±0.61).

***Heart disease***

13 Occupations: In Table 3, the prevalence of heart disease by the different occupations is presented by age, gender, race, ethnicity, and insurance availability as well as the estimated US population numbers. Among the 13 occupations, Protective service workers experienced the highest overall prevalence (7.16±0.59), while Handlers, equipment cleaners, helpers, laborers experienced the lowest (4.54±0.33). Among the age-gender-race-ethnicity-insurance availability subgroups, 65 year and older Transportation/ material moving workers experienced the highest overall prevalence (27.57±2.97), while other race Machine operators, assemblers, inspectors workers experienced the lowest (1.58±0.59).

41 Occupations**:** In Table 3, the prevalence for heart disease by the different occupations is presented by age, gender, race, ethnicity, and insurance availability as well as the estimated US population numbers. Among the 41 occupations, Other professional specialty occupation workers experienced the highest overall prevalence (8.68±0.53), while Construction laborers experienced the lowest (4.39±0.63). Among the age-gender-race-ethnicity-insurance availability subgroups, 65 year and older Other transportation except motor vehicles workers experienced the highest overall

prevalence (51.94±35.30), while other race and Black Forestry and fishing occupations; other race and Hispanic Other transportation except motor vehicles; Insured, Black, Hispanic, and Other race Architects and surveyors; Hispanic, 65 year and older and other race Computer equipment operators; other race Farm operators and managers workers experienced the lowest (0.00±0.00, based on an n of 7, 14, 4, 6, 17, 15, 27, 18, 48, 1, 38, and 19, respectively).

8 NORA Industry Groups: In Table 3, the prevalence for heart disease by the different occupations is presented by age, gender, race, ethnicity, and insurance availability as well as the estimated US population numbers. Among the NORA Sectors, Healthcare and social assistance workers experienced the highest overall prevalence (7.72±0.20), while Construction workers experienced the lowest (4.85±0.23). Among the age-gender-race-ethnicity-insurance availability subgroups, 65 year and older Mining workers experienced the highest overall prevalence (41.68 ±13.61), while Hispanic Agriculture, forestry, fishing workers experienced the lowest (2.32±0.48).

***Stroke***

13 Occupations: In Table 3, the prevalence of stroke by the different occupations is presented by age, gender, race, ethnicity, and insurance availability as well as the estimated US population numbers. Among the 13 occupations, Private household workers experienced the highest overall prevalence of stroke (1.14±0.33), while Professional specialty workers experienced the lowest (0.39±0.05). Among the age-gender-race-ethnicity-insurance availability subgroups, 65 year and older Transportation/ material moving workers experienced the highest overall prevalence (5.35±1.64), while other race Farming, forestry, fishing; other race Private household; Insured Technicians/related support; other race Protective service workers experienced the lowest (0.00±0.00, based an n of 250, 118, 406, and 181, respectively).

41 Occupations**:** In Table 3, the prevalence rate of stroke by the different occupations is presented by age, gender, race, ethnicity, and insurance availability as well as the estimated US population numbers. Among the 41 occupations, Other protective service Occupations workers experienced the highest overall prevalence of stroke (1.50±0.34), while Health diagnosing occupation workers experienced the lowest (0.23±0.14). Among the age-gender-race-ethnicity-insurance availability subgroups, 65 year and older Computer equipment operators workers experienced the highest overall prevalence (100.00±0.00), while insured, other race, Black, Female, Hispanic, and 65 year and older Architects and surveyors; Hispanic, other race, insured, male Computer equipment operators; Other race, Hispanic, female Construction laborers; Black, insured Engineers, plus 20 other occupational groups workers experienced the lowest (0.00±0.00 based on relatively small sample sizes).

8 NORA Industry Groups: In Table 3, the prevalence of stroke by the different occupations is presented by age, gender, race, ethnicity, and insurance availability as well as the estimated US population numbers. Among the NORA Sectors, Mining workers experienced the highest overall prevalence (1.33±0.57), while Manufacturing workers experienced the lowest (0.51±0.05). Among the age-gender-race-ethnicity-insurance availability subgroups, 65 year and older Mining workers experienced the highest overall prevalence (7.20±6.92), while Black and other race Mining workers experienced the lowest (0.00±0.00, based on an n of 28 and 20, respectively).

***Emphysema***

13 Occupations: In Table 3, the prevalence rate for emphysema by the different occupations is presented by age, gender, race, ethnicity, and insurance availability as well as the estimated US population numbers. Among the 13 occupations, Transportation/ material moving workers experienced the highest overall prevalence of emphysema (1.16±0.16), while Professional specialty workers experienced the lowest (0.25±0.03). Among the age-gender-race-ethnicity-insurance availability subgroups, other race Transportation/ material moving workers experienced the highest

overall prevalence rate (5.29±1.45), while other race Farming, forestry, fishing; other race and 65 year and older Technicians/related support workers; Hispanic Protective service; Black Private household experienced the lowest (0.00±0.00, based on an n of 250, 432, 427, 81, and 149, respectively).

41 Occupations**:** In Table 3, the prevalence of emphysema by the different occupations is presented by age, gender, race, ethnicity, and insurance availability as well as the estimated US population numbers. Among the 41 occupations, Forestry and fishing workers experienced the highest overall prevalence of emphysema (2.49±1.81), while Architects and surveyors and Other transportation except motor vehicles workers experienced the lowest (0.00±0.00, based on an n of 261 and 181 workers, respectively). Among the age-gender-race-ethnicity-insurance availability subgroups, 65 year and older Mechanics and repairers workers experienced the highest overall prevalence (9.48±3.20), while thirty-one occupational classes experienced the lowest (0.00±0.00, based on variably small sample sizes).

8 NORA Industry Groups: In Table 3, the prevalence of emphysema by the different occupations is presented by age, gender, race, ethnicity, and insurance availability as well as the estimated US population numbers. Among the NORA groups, Manufacturing workers experienced the highest overall prevalence (0.68±0.07), while Healthcare and social assistance workers experienced the lowest (0.40±0.05). Among the age-gender-race-ethnicity-insurance availability subgroups, 65 year and older Mining workers experienced the highest overall prevalence (6.45±6.25), while Black and other race Agriculture, forestry, fishing workers, and Female, Black, other race Mining workers experienced the lowest (0.00±0.00, based on an n of 169, 240, 75, 28, 20, respectively).

***Asthma***

13 Occupations: In Table 3, the prevalence of asthma by the different occupations is presented by age, gender, race, ethnicity, and insurance availability as well as the estimated US population numbers. Among the 13 occupations, Service occupations except protective/household workers experienced the highest overall prevalence of asthma (10.58±0.28), while Farming, forestry, fishing workers experienced the lowest (6.83±0.53). Among the age-gender-race-ethnicity-insurance availability subgroups, insured Technicians/related support workers experienced the highest overall prevalence (12.63±1.76), while other race Farming, forestry, fishing workers experienced the lowest (2.64±0.95).

41 Occupations**:** In Table 3, the prevalence of asthma by the different occupations is presented by age, gender, race, ethnicity, and insurance availability as well as the estimated US population numbers. Among the 41 occupations, Health service workers experienced the highest overall prevalence (11.53±0.57), while Farm operators and managers experienced the lowest (5.53±0.88). Among the age-gender-race-ethnicity-insurance availability subgroups, insured Architects and surveyors workers experienced the highest overall prevalence (27.35±16.56), while 65 year and older Computer equipment operators; other race Forestry and fishing occupations; 65 year and older Police and firefighters; 65 year and older Officials and administrators public admin; 65 year and older, other race, Hispanic, insured Other transportation except motor vehicles workers experienced the lowest (0.00±0.00, based on variably small sample sizes).

8 NORA Industry Groups: In Table 3, the prevalence of asthma by the different occupations is presented by age, gender, race, ethnicity, and insurance availability as well as the estimated US population numbers. Among the NORA Sectors, Healthcare and social assistance workers experienced the highest overall prevalence (10.59±0.24), while Agriculture, forestry, fishing workers experienced the lowest (6.83±0.52). Among the age-gender-race-ethnicity-insurance availability subgroups, Female Mining workers experienced the highest overall prevalence (12.08±4.31), while other race Agriculture, forestry, fishing workers experienced the lowest (2.67±0.99).

***Cancer***

13 Occupations: In Table 3, the prevalence of cancer by the different occupations is presented by age, gender, race, ethnicity, and insurance availability as well as the estimated US population numbers. Among the 13 occupations, Professional specialty workers experienced the highest overall prevalence (4.79±0.15), while Handlers, equipment cleaners, helpers, laborer experienced the lowest (1.70±0.18). Among the age-gender-race-ethnicity-insurance availability subgroups, 65 year and older Professional specialty workers experienced the highest overall prevalence (21.36±1.52), while other race Farming, forestry, fishing workers experienced the lowest (0.51±0.41).

41 Occupations**:** In Table 3, the prevalence of cancer by the different occupations is presented by age, gender, race, ethnicity, and insurance availability as well as the estimated US population numbers. Among the 41 occupations, Officials and administrators public administration workers experienced the highest overall prevalence of cancer (7.36±0.90), while Construction laborers experienced the lowest (1.15±0.31). Among the age-gender-race-ethnicity-insurance availability subgroups, 65 year and older Other transportation except motor vehicles workers experienced the highest overall prevalence (51.94±35.30, based on only 1 worker), while twenty groups of workers experienced the lowest (0.00±0.00).

8 NORA Industry Groups: In Table 3, the prevalence of cancer by the different occupations is presented by age, gender, race, ethnicity, and insurance availability as well as the estimated US population numbers. Among the NORA Sectors, Healthcare and social assistance workers experienced the highest overall prevalence (4.72±0.16), while Construction workers experienced the lowest (2.70±0.19). Among the age-gender-race-ethnicity-insurance availability subgroups, 65 year and older Mining workers experienced the highest overall prevalence (29.68±9.59), while Black Mining workers experienced the lowest (0.00±0.00, based on 28 workers).

***Diabetes***

13 Occupations: In Table 3, the prevalence of diabetes by the different occupations is presented by age, gender, race, ethnicity, and insurance availability as well as the estimated US population numbers. Among the 13 occupations, Private household workers experienced the highest overall prevalence (6.43±0.98), while Technicians/related support workers experienced the lowest (3.41±0.27). Among the age-gender-race-ethnicity-insurance availability subgroups, 65 year and older Handlers, equipment cleaners, helpers, laborers workers experienced the highest overall prevalence of diabetes (19.37±3.45), while other race Private household workers experienced the lowest (0.97±0.57).

41 Occupations**:** In Table 3, the prevalence of diabetes by the different occupations is presented by age, gender, race, ethnicity, and insurance availability as well as the estimated US population numbers. Among the 41 occupations, Health service workers experienced the highest overall prevalence of diabetes (7.00±0.53), while Health diagnosing occupation workers experienced the lowest (1.29±0.34). Among the age-gender-race-ethnicity-insurance availability subgroups, 65 year and older Other transportation except motor vehicles workers experienced the highest overall prevalence (51.94± 35.30), while twelve groups of workers experienced the lowest (0.00±0.00 based on variably small sample sizes).

8 NORA Industry Groups: In Table 3, the prevalence of diabetes by the different occupations is presented by age, gender, race, ethnicity, and insurance availability as well as the estimated US population numbers. Among the NORA Sectors, Healthcare and social assistance workers experienced the highest overall prevalence of diabetes (5.13±0.18), while Construction workers experienced the lowest (3.37±0.22). Among the age-gender-race-ethnicity-insurance availability

subgroups, Black Mining workers experienced the highest overall prevalence of diabetes (19.42±8.49), while Hispanic Mining workers experienced the lowest (3.37±0.22).

## CONCLUSIONS

This Occupations and Health Disparities Monograph of all currently employed adults 18 years or older from the 1997-2004 NHIS surveys demonstrated health disparities as measured by disability (lost work days and self rated health) and health conditions among certain occupational groups compared to all others. This Monograph confirmed some possible associations between particular occupations (and their exposures) and certain age-gender-race-ethnicity-insurance availability subpopulations already recognized in the literature. This Occupation and Health Disparities Monograph also demonstrated possible new associations between occupation and these subpopulations with respect to their health. In general, these new associations were detectable due to the large representative sample size of the US workforce provided by the NHIS surveys. Furthermore, these possible new associations can be considered "hypothesis generating" and worthy of future investigation and research.

In general, among the occupations, more skilled "white collar" workers were more likely to report increased measures of disability (ie. lost work days and bed days), but less likely to report poor health or negative health conditions (with the exception of cancer).(Fleming; Lee, Fleming et al. 2006) This may be due to the increased likelihood of both paid sick days and health insurance among these more skilled workers, allowing them to take days off from work, while "blue collar" workers and their families might be less likely to have such work benefits.(Arheart, Lee et al. 2006) It is also interesting to speculate about the possible under-reporting of health conditions among the "blue collar" workers due to their lack of access to medical care and thus possible under-diagnosis of these conditions, as may be reflected in their increased self-reporting of poor health. Nevertheless, within particular occupations, Hispanic, black and "other race" workers were often more likely to experience increased prevalence of negative health conditions. Of note, these same worker subgroups were more likely to report acute and chronic disabilities, poor self-rated health, and more negative health conditions relative to all workers. (Fleming 2004) It is also interesting to consider the pattern of increased (and possibly underreported) negative health conditions among workers 65 years and older since they represent a rapidly growing segment of the US workforce.(Wegman 1999; Fleming, Lee et al. (in press))

In a separate analysis, the investigators have modeled acute and chronic disability adjusting for age, gender, race/ethnicity, and education in the entire NHIS worker database, as well as comparing disability among farmers and pesticide applicators with all other US workers.(Fleming; Gomez-Marin, Fleming et al. 2004) Among all NHIS workers, being of a younger age was a significant risk factor for reporting acute disability; older age was a significant risk factor in a dose response fashion for reporting chronic disability and poor health status. Of note, using the same NHIS database, Zwerling et al (Zwerling, Sprince et al. 1995; Zwerling, Sprince et al. 1996; Zwerling, Sprince et al. 1996; Daltroy, Iversen et al. 1997; Zwerling, Whitten et al. 1997; Peterson and Zwerling 1998; Zwerling, Sprince et al. 1998; Zwerling, Whitten et al. 1998; Zwerling, Whitten et al. 2003) found a significantly increased injury risk among older and disabled US workers. As with other investigators, Gomez Marin et al (Gomez-Marin, Fleming et al. 2004) also found that older female uneducated workers were at significantly higher risk of chronic disability and experienced poor health status compared to all other US workers. Less educated older female workers are more likely to have poorly paying jobs with significant physical labor and longer hours.

Several health conditions among those examined in this Monograph have been traditionally associated with occupational exposures including Asthma, Emphysema, and Cancer (Nathell, Malmberg et al. 2000; Karjalainen, Kurppa et al. 2002; Arif 2003; Trupin, Earnest et al. 2003; Le Moual 2004; MacDonald, Dixon et al. 2004; Rosengren 2004; Fleming 2005; McDonald 2005; Rosenstock 2005) Although cancer mortality has been associated with a few specific occupations (such as

farmers and pesticides)(Fleming 2005), in this study, it was the higher socio-economic class workers (e.g. Professional specialty workers) with the increased risk of cancer prevalence. Again, this might be explained by "under-diagnosis" in lower class workers who may have less access to healthcare. Asthma, emphysema and respiratory diseases have been reported in a variety of occupations associated with a range of dust and chemical exposures((NIOSH) 2003). Transportation workers and Health service workers seemed to be particularly at risk for reported prevalence of asthma; Transportation workers can be exposed to diesel fumes while Health service workers are not only more likely to be exposed to infectious respiratory agents repeatedly but also to respiratory allergens such as latex and gluteraldehyde.(Arif 2003; McDonald 2005) Traditionally, occupation has been evaluated as a socio-economic risk factor for cardiovascular disease (including hypertension, stroke, heart disease, and even diabetes).(Mikuni 1983; Steenland, Johnson et al. 1997; Leigh 1998; Pickering 1999; Hart 2000). It is interesting to note that particularly in the NORA Industry Sectors, there is a consistent risk of all types of cardiovascular disease for miners – a finding that is consistent with previous research by Costello et al. (Costello, Ortmeyer et al. 1975)

Finally, when examining the data by NORA Sectors, the Mining and the Healthcare and Social Assistance Sectors reported the highest prevalence of negative health conditions: hypertension and stroke for the Mining Sector workers, and heart disease, asthma, cancer, and diabetes for the Healthcare and Social Assistance Sector workers, respectively. Of note, a ranking of US workers based on analysis of 1986-1994 NHIS participants listed social workers, psychologists, nursing aids, and licensed practical nurses among the top ten occupational groups with the worst morbidity among the 206 examined worker groups (Lee et al, 2006). When looking at the age-gender-race-ethnicity-insurance availability subcategories among the NORA Sectors, 65 years and older Mining workers reported an increased prevalence of hypertension, heart disease, stroke, emphysema, and cancer, while female Mining workers reported the highest prevalence of asthma and Black Mining workers the highest prevalence of diabetes.

***Limitations***

These analyses are subject to data limitations evident in previous epidemiologic studies with similar data sets. One important limitation in interpreting the Morbidity Rates is the small sample size in some subgroups, particularly those in the 41 Occupational Subgroups further divided by age, gender, race, ethnicity, and insurance availability. Therefore, as noted above, any increased rates must be viewed as hypothesis-generating only. Other limitations included: the self-report and cross sectional nature of the initial data which might lead to underestimation of the true health situation since really sick people leave the work force (part of the healthy worker effect); lack of individual exposure measures; and occupational misclassification in general due to the use of "current job" as a surrogate for "longest held job," as well as misclassification of occupation related exposures. With regards to the latter issue, two occupational health related supplements were administered to NHIS participants, one in 1986 and the second in 1988. We used previously published Kappa values from these two supplements to estimate the extent to which "current job" reflected "longest held job" within each occupational category.(Gomez-Marin, Fleming et al. 2005) The use of the US worker population as the major comparison population is appropriate for controlling for the healthy worker effect and other biases.(Monson 1990; Cooper, Buffler et al. 1993; Checkoway 2004) Previous work using the NHIS database has shown that certain occupational groups, such as farmers, smoke and drink less than many other worker groups (15-29% prevalence) which may explain some of the study findings.(Sterling and Weinkam 1976; Brackbill, Frazier et al. 1988; Sterling and Weinkam 1989; Sterling and Weinkam 1990; Brackbill, Cameron et al. 1994; Nelson, Emont et al. 1994; Lee, LeBlanc et al. 2004; Lee, Fleming et al. 2006) Confounding data such as tobacco use and obesity are available for subpopulations of the NHIS database but were not used in this study; however, tobacco use data are available for use by researchers at the Study Website (www.UMiamiORG.com). (Lee, LeBlanc et al. 2004; Caban, Lee et al. 2005; Lee, Fleming et al. 2006) The NHIS data (including occupation) were based largely on self-report (by the

individual or proxy) without objective confirmation. The limitations of these data are an important limitation on any conclusions that can be drawn from these analyses.

Ultimately, this analysis of the NHIS data strongly suggested that selected occupational groups andgender and race-ethnicity subpopulations should be important target populations for occupational illness/disability prevention and intervention.(Partanen, Johansson et al. 2002) Researchers in occupational health are urged to seek out this important and publicly available resource. The NHIS database and mortality follow-up represent a probability sample of the entire US population, with the ability to compare both morbidity and mortality among US workers. Furthermore, as noted by NIOSH (NIOSH 1997) and the English Registrar's Decennial Reports (Drever 1995), databases such as the NHIS surveys and mortality follow-up can be used not only to target studies of work-related conditions and to add to the body of evidence generated from epidemiologic studies, but also to provide surveillance data for establishing priorities, and for tracking progress towards the elimination of preventable diseases and mortality.
